# **Cyber Threat Intelligence Research**

Kthreatconnect.com/blog/crimsonias-listening-for-an-3v1l-user/

January 27, 2021

#### **Executive Summary**

<u>CrimsonIAS</u> is a Delphi-written backdoor dating back to at least 2017 that enables operators to run command line tools, exfiltrate files, and upload files to the infected machine. CrimsonIAS is notable as it listens for incoming connections only; making it different from typical Windows backdoors that beacons out. The characteristics found in CrimsonIAS's execution flow suggest a connection to <u>Mustang Panda</u> (aka BRONZE PRESIDENT, RedDelta) PlugX samples. Based on those non-unique characteristics, ThreatConnect assesses with low confidence that CrimsonIAS is an additional tool in Mustang Panda's repertoire. Industry reporting assesses with varying levels of confidence that Mustang Panda is a Chinese espionage actor that has conducted operations in <u>Mongolia</u>, <u>Vietnam</u>, and <u>Hong Kong</u> among other locations. According to <u>fellow researchers</u>, Mustang Panda targets non-government organizations (NGOs), law enforcement organizations, and political entities.

#### Discovery

ThreatConnect identified CrimsonIAS while hunting for XOR encrypted PlugX binaries. The CrimsonIAS backdoor is encrypted similarly to recent MustangPanda PlugX samples, which piqued our interest.

Encrypted SHA256: acfd58369c0a7dbc866ad4ca9cb0fe69d017587af88297f1eaf62a9a8b1b74b4

Decrypted SHA256: 891ece4c40a7bf31f414200c8c2c31192fd159c1316012724f3013bd0ab2a68e

### **CrimsonIAS Analysis**

The developers behind CrimsonIAS wrote this backdoor using Delphi. They also added some features that changed the normal execution flow starting with shell code embedded in the MZ header. Windows executables are not designed to execute code from the MZ header; they have a dedicated section (outside of the MZ header) for executable code. The actor is able to work around this design choice to start execution in the MZ header based on how we suspect the binary is loaded. This shell code calls a reflective loader function which resolves additional library functions needed before jumping to the malware's actual entrypoint. The binary was also XOR encrypted with a 10 byte XOR key prepended to the binary (<u>T1140</u>: <u>Deobfuscate/Decode Files or Information</u>). All of these are also seen in Mustang Panda's PlugX samples.

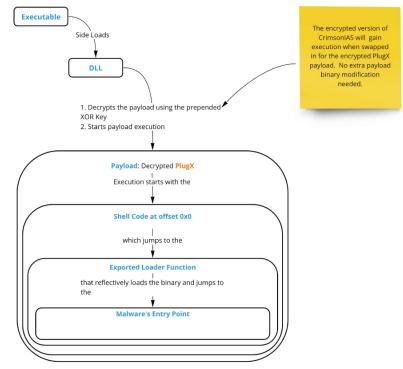

Figure 1: Binary Loading Sequence

This backdoor spins up a listener and awaits the operator's commands to run command line tools, exfiltrate files, and upload files to the infected machine. Prior to spinning up the network listener, CrimsonIAS launches netsh.exe to open a port on the local machine (<u>T1562.004</u>: <u>Impair Defenses: Disable or Modify System Firewall</u>). This sample opens port 80.

Figure 2: netsh command construction

# **Command and Control**

When receiving network traffic, the listener's handler first checks for the presence of the marker 0x33669966 (T1205: Traffic Signaling). If it matches, then the handler proceeds to parse the first 24 bytes.

🗾 🚄 🖼		
cmp	<pre>[edi+COMMAND_HEADER.command_marker],</pre>	<mark>33669966h</mark>
jnz	short loc_41C78C	

Figure 3: Marker Check

The first 24 bytes make up the command header; however, only the first three DWORDs appear to be used.

Field	Size	Offset
Command Marker	DWORD	0x0
Command Code	DWORD	0x4
Command Buffer Size	DWORD	0x8

The command buffer starts at offset 24 (0x18) and its content differs based upon the command code specified.

The three command codes are:

- 0x6600 : Run Command (T1059.003: Command and Scripting Interpreter: Windows Command Shell)
- 0x7701 : Receive File (<u>T1105: Ingress Tool Transfer</u>)
- 0x7702 : Send File (T1041: Exfiltration Over C2 Channel)

Figure 4: Command Switch Table

A null preserving XOR encryption algorithm is used to hide the buffer's contents (<u>T1573.001: Encrypted Channel: Symmetric Cryptography</u>). All of the samples found use the same single byte XOR key 0x85.

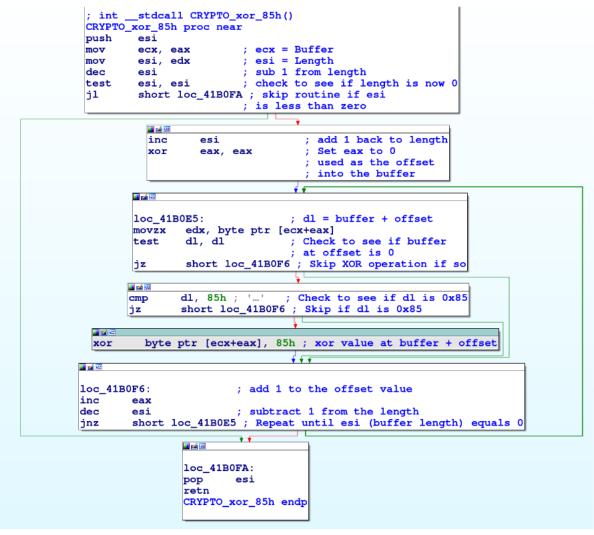

Figure 5: XOR Encryption

# **Command and Control Recreation**

After reversing the backdoor's network byte parser, we recreated parts of the command and control (C2) server to elicit responses from it. Here the backdoor responds to our command telling it to execute "net user evil 3v11/add".

00000000 66	99 66	33 00	66 00 00	56 00 0	0 00 00	00 00 00	f.f3.f V

0000007C	00 00	00 00	00 00 00	00				

Figure 6: Communication Capture

Notice both the sent and received responses start with 0x33669966 (0x66996633 on the network); enabling fingerprinting of the network traffic. The response buffer reads: "The command completed successfully."

# **Mustang Panda Connection**

We assess with low confidence that CrimsonIAS is associated with Mustang Panda. The similarities with how the binary was packaged along with how it's launched are the basis for this connection.

Inspecting Mustang Panda PlugX samples identified last year, we observed these three pertinent characteristics:

#### 1 - Encrypted with a 10 byte XOR key prepended to the encrypted binary

Mustang Panda PlugX	CrimsonIAS
Construint         Constru	XOR Key         Null Byte Delimiter         Start of MZ File           00000000         44         48         47         46         56         44         60         69         12         af         46         56           0000000         4e         74         3a         34         04         11         c3         b         c7         95         f3         c6         66         be         97           Figure 8:         Prepended XOR Key         (acfd58369c0a7dbc866ad4ca9cb0fe69d017587af88297f1eaf6         2a9a8b1b74b4)         acfd58369c0a7dbc866ad4ca9cb0fe69d017587af88297f1eaf6

Figure 7 and 8 show a prepended XOR key separated by a null byte from the encrypted payload. Over the past 8 months we've been monitoring this technique and, outside of this one CrimsonIAS sample, all the other uploaded samples have been the PlugX associated with Mustang Panda. We acknowledge during the last two months of 2020 that two samples deviated from the 10 byte XOR key length; however, the overwhelming majority used a 10 byte prepended XOR key.

#### 2 - Matching shell code at the start of the MZ header (minus the offset value)

Mustang Panda PlugX				CrimsonIAS				
isassembly				Disassembly				
Address		Bytes	Disassembly	Address	Offset	Bytes	Disassembly	
6×0	0×0	4D	dec ebp	8x8	6×8	4D	dec ebp	
0×1	0×1		pop edx	0×1			pop edx	
8x2	θx2	E8 68 68 68 68	call 7	θx2	8x2	E8 88 88 88 88		
6×7			pop ebx	8×7				
0×8	8×8		push edx	0×0	0×0		push edx	
6x9	8×9		inc ebp	θ×9	8×9		inc ebp	
6xa	θxa		push ebp	8xa	6xa		push ebp	
0xb	0×b	8B EC	mov ebp, esp	θ×b	0xb	8B EC	mov ebp, esp	
0×d	0×d	81 C3 39 11 00 00	add ebx, 0x1139	θxd	0×d	81 C3 BD BF 01 00	add ebx, 0x1bfbd	
0×13	0×13	FF D3	call ebx	θx13	6x13	FF D3		
8×15	0×15		leave	0×15	8x15			
0×16	0×16		ret	0×16	0×16			
						Offset to the exporte This is the only part th	d Loader Function at differs but that is to be expected	
092A74E	MZ Header S C57E53D449 0045D416F0	9E0F0D4053F8A	DB6E1BB6CA3		40a7bf31f4	Shell Code 14200c8c2c311	92fd159c1316012724f	

Shell code in the MZ header is not exclusive to Mustang Panda, as tools like Cobalt Strike make use of this; however this set of bytes (shown in figures 9 and 10) we've only seen in files related to Mustang Panda over the past few months.

#### 3 – Exported Loader function

Mustang Panda PlugX			CrimsonIAS				
Exports			🛱 Exports	1			
Name	Address	Ordinal	Name	Address	Ordinal		
Hume		ordinat	dbkFCallWrapperAddi	0042662C	1		
🛚 Loader	10001D40	1	<pre>dbk_fcall_wrapper</pre>	0040BB34	2		
🛛 DllEntryPo	oint 1001604B	[main entry]	🛚 Loader	0041CBC4	3		
iqure 11: DLL Ev	norte		DllEntryPoint	00420558	[main entry]		
Figure 11: DLL Exports (D92A74EC57E53D449E0F0D4053F8ADB6E1BB6CA339284 E1E0045D416FCD022A6)			Figure 12: DLL Exports (891ece4c40a7bf31f414200 13bd0ab2a68e)	)c8c2c31192fd1	59c1316012724f		

Both samples also make use of a reflective loader technique which they export under the name Loader. Searching VTI for this exported function leads to a fair number of results not tied to Mustang Panda samples; so the presence of this export is not unique enough.

Finally, we successfully launched CrimsonIAS by taking a Mustang Panda PlugX archive (complete with the DLL sideloading executable and the sideloaded DLL) and swapping out the encrypted PlugX DLL with the encrypted CrimsonIAS DLL (<u>T1574.002</u>: <u>Hijack Execution Flow</u>: <u>DLL Side-Loading</u>).

Grouping these characteristics together is the basis for the CrimsonIAS connection with Mustang Panda. The reasoning behind the low confidence is the fact that the first two techniques should be trivial to implement/copy and that the third is not unique to Mustang Panda; increasing the likelihood it could be a copycat, false flag, or inadvertent consistency. Additional information on organizations targeted, affected regions, the complete payload, inbound communications, or any associated incidents would potentially help us reassess our confidence in CrimsonIAS' association to Mustang Panda.

### **Evolution**

VirusTotal shows that the first sample was uploaded back in 2018.

The earliest compile time found suggests this backdoor has been around since at least 2017. The three samples with the compile time 2018-05-25 03:19:15 are the same sample with just the listen on port number changed; probably after compilation.

Overall CrimsonIAS's primary functionality remains consistent over the years. The primary difference lies in how the malicious code is executed. The earlier samples relied on calling the exported function CPIApplet that would register and launch a Windows service that then executes the backdoor functionality (<u>T1569.002</u>: <u>System Services</u>: <u>Service Execution</u>). The file

63e144fbe0377e0c365c126d2c03ee5da215db275c5376e78187f0611234c9b0 is an exception as the exported function CPIApplet does not create a service but it immediately starts up the backdoor.

The latest sample moved away from this technique and it now makes use of a reflective loader technique that is seen across different malware families. This change along with the prepended XOR key and the shellcode provide hints to who might be behind this backdoor.

### Conclusion

ThreatConnect believes that Mustang Panda will continue to be active and adapt their toolset as needed to meet their objectives against largely near-abroad targets. The backdoor, CrimsonIAS, passively awaits commands, implying that the actor has some means of proxying/accessing the target's network or, more likely, that the machine targeted is exposed to the public Internet. We encourage entities who think they might have been targeted by Mustang Panda to check for the presence of programs listening for external inbound connections and inspect further if something is found. Verify carefully as the presence of programs listening for inbound connections does not necessarily mean that the machine is compromised.

#### Naming Convention Note

We generally abstain from adding a new name for malware and threats where other industry reporting has already done so. Two exceptions where we may use our own naming convention:

- When we are unsure whether our findings are consistent with activity sets other organizations have described and named. In this case, we will attempt to describe the overlap and differences between those previously named sets and the activity we're describing.
- When we are describing a previously unnamed malware or threat.

The latter is the case here. Our naming convention is intended to help describe the assessed origin of the threat or malware, along with another identifier that is specific to the entity. In this case, we are using *Crimson* to refer to the malware's assessed Chinese origin, and *IAS* to refer to the Internet Authentication Service (IAS) binary string previously described.
