

Zircolite vs Defense Evasion & Nobellium FoggyWeb

 holisticinfosec.io/post/2021-09-28-zircolite/

I'm pleased to be back sharing outstanding tools for security practitioners with you after an extended time out to finish my [Ph.D.](#)

Here now, in our 145th installment of toolsmith, we discuss [Zircolite](#), a standalone and fast SIGMA-based detection tool for EVTX or JSON, a fine tool brought to us courtesy of [@waggabat](#). Zircolite's GitHub repo tells you absolutely everything you need to know, and the [documentation](#) is more than adequate, so I'll repeat only this:

- Zircolite is a standalone tool written in Python 3 allowing to use SIGMA rules on Windows event logs
- Zircolite can be used directly on the investigated endpoint or in your favorite forensic/detection lab
- Zircolite is fast and can parse large datasets in just seconds
- Zircolite can handle EVTX files and JSON files as long as they are in JSONL/NDJSON format
- Zircolite can be used directly in Python or you can use the binaries provided in releases

As you install Zircolite via a git clone to your preferred path, install the additional requirements via `pip install -r requirements.txt`.

Running Zircolite is as easy as the likes of `python zircolite.py --evtx logs --ruleset rules/rules_windows_generic.json`.

The rulesets provided are a set of SIGMA-based generic Windows rules and Sysmon rules. We owe [Florian Roth](#) and other many thanks for [SIGMA](#), a true SOC work horse.

I'm particularly fond of actions we defenders can take to detect defense evasion. As such, our first test scenario is oriented accordingly. I created a `logs` directory in my Zircolite path and copied 16 [defense evasion-specific EVTX log samples](#) from [Samir's killer Windows EVTX Samples repo](#). Love this resource! Thereafter, a quick run of Zircolite using the Sysmon rules provided immediate findings (two seconds) as seen in **Figure 1**.

```
PowerShell x Command Prompt x + v
C:\tools\Zircolite>python zircolite.py --evtX logs --ruleset rules/rules_windows_sysmon.json

Figure 1: Zircolite run with Sysmon rules

Oh, wait. You're not running Sysmon everywhere possible? Tsk, tsk. Download [Sysmon](#), and use [SwiftOnSecurity's](#) rocking good [config file template](#) with default high-quality event tracing. Thanks as always to [Mark](#) and [Thomas](#) for the indispensable masterpiece that is Sysmon. Zircolite findings are written out to `detected_events.json` in the Zircolite parent directory. In keeping with **Figure 2** represents the first of 82 detections of code injection with PowerShell.

```

Figure 2: Zircolite detected event

As you can see, Zircolite can be adapted to almost any Windows-centric detection scenario as long as the events are written to EVT-X. With Sysmon running Zircolite is an absolute no-brainer.

But wait! You need a GUI? No problem. Unzip the contents of *zircogui.zip* found in the gui directory. Revisiting our Nobellium FoggyWeb scenario, I ran: `python zircolite.py --evtx logs/sysmon.evtx --ruleset rules/rules_windows_nobellium_filedrop.json --template templates/exportForZircoGui.tpl --templateOutput gui/data.js`

The result, as seen in **Figure 4**, represents a convenient way to hunt about in numerous events per a MITRE ATT&CK category or an alert level.

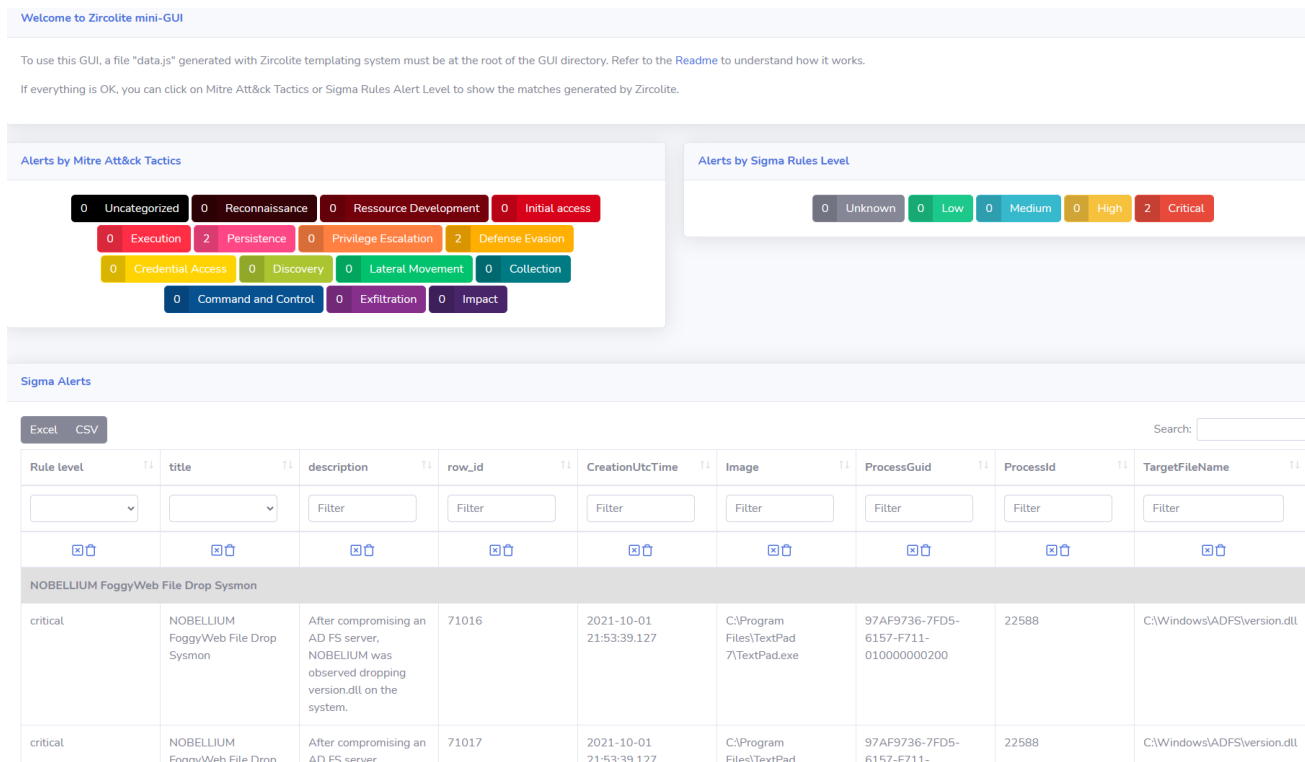

Figure 4: Zircolite GUI

I'm quite glad to be back at the keyboard working useful cybersecurity tooling scenarios with you. Zircolite represented a golden opportunity to do so and couldn't have coincided more nicely than with the recently released Nobellium FoggyWeb analysis. Great work from @waggabat, I hope they keep it up.

Cheers...until next time.
