HermeticWiper | New Destructive Malware Used In Cyber Attacks on Ukraine

sentinelone.com/labs/hermetic-wiper-ukraine-under-attack/

Juan Andrés Guerrero-Saade

This post was updated Feb 28th 2022 to include new IOCs and the PartyTicket 'decoy ransomware'.

Executive Summary

- On February 23rd, the threat intelligence community began observing a new wiper malware sample circulating in Ukrainian organizations.
- Our analysis shows a signed driver is being used to deploy a wiper that targets Windows devices, manipulating the MBR resulting in subsequent boot failure.
- This blog includes the technical details of the wiper, dubbed HermeticWiper, and includes IOCs to allow organizations to stay protected from this attack.
- This sample is actively being used against Ukrainian organizations, and this blog will be updated as more information becomes available.
- We also analyze a 'ransomware', called PartyTicket, reportedly used as a decoy during wiping operations.
- SentinelOne customers are protected from this threat, no action is needed.

Background

On February 23rd, our friends at Symantec and ESET research tweeted hashes associated with a wiper attack in Ukraine, including one which is not publicly available as of this writing.

We started analyzing this new wiper malware, calling it 'HermeticWiper' in reference to the digital certificate used to sign the sample. The digital certificate is issued under the company name 'Hermetica Digital Ltd' and valid as of April 2021. At this time, we haven't seen any legitimate files signed with this certificate. It's possible that the attackers used a shell company or appropriated a defunct company to issue this digital certificate.

HermeticWiper Digital Signature

This is an early effort to analyze the first available sample of HermeticWiper. We recognize that the situation on the ground in Ukraine is evolving rapidly and hope that we can contribute our small part to the collective analysis effort.

Technical Analysis

At first glance, HermeticWiper appears to be a custom-written application with very few standard functions. The malware sample is 114KBs in size and roughly 70% of that is composed of resources. The developers are using a tried and tested technique of wiper malware, abusing a benign partition management driver, in order to carry out the more damaging components of their attacks. Both the Lazarus Group (<u>Destover</u>) and APT33 (<u>Shamoon</u>) took advantage of Eldos Rawdisk in order to get direct userland access to the filesystem without calling Windows APIs. HermeticWiper uses a similar technique by abusing a different driver, <u>empntdrv.sys</u>.

[— Туре	Size	ID	Name —

	RCDATA	9626	0	DRV_XP_X86

HermeticWiper resources containing EaseUS Partition Manager drivers

The copies of the driver are ms-compressed resources. The malware deploys one of these depending on the OS version, bitness, and SysWow64 redirection.

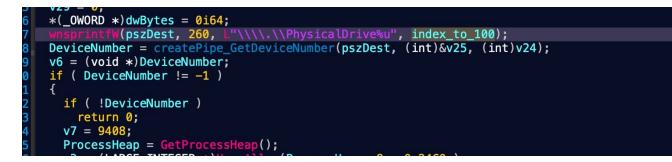

EaseUS driver resource selection

The benign EaseUS driver is abused to do a fair share of the heavy-lifting when it comes to accessing Physical Drives directly as well as getting partition information. This adds to the difficulty of analyzing HermeticWiper, as a lot of functionality is deferred to **DeviceIoControl** calls with specific IOCTLs.

MBR and Partition Corruption

HermeticWiper enumerates a range of Physical Drives multiple times, from 0-100. For each Physical Drive, the \\.\EPMNTDRV\ device is called for a device number.

The malware then focuses on corrupting the first 512 bytes, the Master Boot Record (MBR) for every Physical Drive. While that should be enough for the device not to boot again, HermeticWiper proceeds to enumerate the partitions for all possible drives.

They then differentiate between FAT and NTFS partitions. In the case of a FAT partition, the malware calls the same 'bit fiddler' to corrupt the partition. For NTFS, the HermeticWiper parses the Master File Table before calling this same bit fiddling function again.

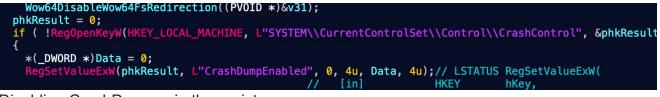

MFT parsing and bit fiddling calls

We euphemistically refer to the bit fiddling function in the interest of brevity. Looking through it, we see calls to Windows APIs to acquire a cryptographic context provider and generate random bytes. It's likely this is being used for an inlined crypto implementation and byte overwriting, but the mechanism isn't entirely clear at this time.

Further functionality refers to interesting MFT fields (**\$bitmap**, **\$logfile**) and <u>NTFS</u> <u>streams</u> (**\$DATA**, **\$I30**, **\$INDEX_ALLOCATION**). The malware also enumerates common folders ('My Documents', 'Desktop', 'AppData'), makes references to the registry ('ntuser'), and Windows Event Logs ("\\\?\\C:\\Windows\\System32\\winevt\\Logs"). Our analysis is ongoing to determine how this functionality is being used, but it is clear that having already corrupted the MBR and partitions for all drives, the victim system should be inoperable by this point of the execution.

Along the way, HermeticWiper's more mundane operations provide us with further IOCs to monitor for. These include the momentary creation of the abused driver as well as a system service. It also modifies several registry keys, including setting the

SYSTEM\CurrentControlSet\Control\CrashControl CrashDumpEnabled key to **0**, effectively disabling crash dumps before the abused driver's execution starts.

Disabling CrashDumps via the registry

Finally, the malware waits on sleeping threads before initiating a system shutdown, finalizing the malware's devastating effect.

A Decoy Ransomware – PartyTicket

On February 24th, 2022, Symantec researchers pointed to a new Go ransomware being used as a decoy alongside the deployment of HermeticWiper. During out analysis we decided to name it PartyTicket based on some of the strings used by the malware developers:

The idea of using a ransomware as a decoy for a wiper is counterintuitive. In particular, a ransomware as poorly coded as PartyTicket is more likely to tie up resources during the execution of an otherwise efficient wiper.

As often happens to amateur Go developers, the malware has poor control over its concurrent threads and the commands it attempts to run. This leads to hundreds of threads and events spawned in our consoles. That is to say, it's a very loud and ineffective ransomware that should fire alerts left and right.

The folder organization and function naming conventions within the binary show the developer's intent for taunting the U.S. Government and the Biden administration.

```
_/C_/projects/403forBiden/wHiteHousE.baggageGatherings
_/C_/projects/403forBiden/wHiteHousE.lookUp
_/C_/projects/403forBiden/wHiteHousE.primaryElectionProcess
_/C_/projects/403forBiden/wHiteHousE.GoodOffice1
_/C_/projects/403forBiden/wHiteHousE.init
C:/projects/403forBiden/main.go
C:/projects/403forBiden/wHiteHousE/wHiteHousE.go
```

Project folders and function names referring to the Biden Administration Similar taunting can be found in the ransom note after execution:

"The only thing that we learn from new elections is we learned nothing from the old!"				
Thank you for your vote! All your files, documents, photoes, videos, databases etc. have been successfully encrypted! Now your computer has a special ID: 10				
Do not try to decrypt then by yourself - it's impossible! It's just a business and we care only about getting benefits. The only way to get your files back is to contact us and get further instuctions. To prove that we have a decryptor send us any encrypted file (less than 650 kbytes) and we'll send you it back being decrypted. This is our guarantee.				
NOTE: Do not send file with sensitive content. In the email write us your computer's special ID (mentioned above).				
So if you want to get your files back contact us: 1) vote: @protonmail.com 2) states 2024@protonmail.com - if we dont't answer you during 3 days				
Have a nice day!				

In trying to understand the execution flow of PartyTicket, we see the

403forBiden.wHiteHousE.primaryElectionProcess() function recursively enumerating folders:

```
V2:
f_itab = *v2;
f_data = v2[1];
f_n_len = *(_QWORD *)substr;
 n_ptr = (uint8 *)(*((__int64 (__golang **)(uint8 *))f_itab + 6))(f_data);
dirname.str = f_n_ptr;
dirname.len = *(_QWORD *)substr;
substra.str = (uint8 *)"Windows";
substra.len = 7LL;
if ( !strings_Contains(dirname, substra) )
  dirnamea.str = f_n_ptr;
  dirnamea.len = f_n_len;
  substrb.str = (uint8 *)"Program Files";
  substrb.len = 13LL;
  if ( !strings_Contains(dirnamea, substrb) )
  {
    if ( (*((unsigned __int8 (__golang **)(uint8 *))f_itab + 3))(f_data) )
      dirname_8[0] = input;
      dirname_8[1].str = (uint8 *)"\\";
      dirname_8[1].len = 1LL;
      dirname_8[2].str = f_n_ptr;
      dirname_8[2].len = f_n_len;
      dirnameb = runtime_concatstring3(0LL, *(string (*)[3])&dirname_8[0].str);
      _C__projects_403forBiden_wHiteHousE_primaryElectionProcess(dirnameb, out);
    }
    else
      dirnamec.str = f_n_ptr;
      dirnamec.len = f_n_len;
      substr[0] = _C__projects_403forBiden_wHiteHousE_lookUp(dirnamec);
      if ( substr[0] )
```

PartyTicket looping over non-system folders

The resulting number of folders will be used as an upperbound for concurrent threads, a mistake by the Go devs as that effectively ties up all of the system's resources. While the files found are all queued into a channel for the threads to reference.

PartyTicket generating concurrent threads

The function indirectly called for each thread is main.subscribeNewPartyMember(). It in turn takes a filename, makes a copy with a <UUID>.exe name and deletes the original file. Then we expect a second loop to relieve that queue of files and run each through a standard Go AES crypto implementation. However, execution is unlikely to get this far with the current design of PartyTicket.

(Thanks to Joakim Kennedy (Intezer) for pointing out this indirect call)

Crypto routine for files queued in the 'salary' channel

Overall our analysis of PartyTicket indicates it to be a rather simple, poorly coded, and loud malware. Its possible role as a decoy ransomware deployed alongside HermeticWiper is more likely to be effective for its accidental hogging of the victim organization's system resources rather than the encryption of files itself. IOCs and Yara rules have been added below.

Conclusion

After a week of defacements and increasing DDoS attacks, the proliferation of sabotage operations through wiper malware is an expected and regrettable escalation. At this time, we have a very small sliver of aperture into the attacks in Ukraine and subsequent spillover into neighboring countries and allies. If there's a silver lining to such a difficult situation, it's seeing the open collaboration between threat intel research teams, independent researchers, and journalists looking to get the story straight. Our thanks to the researchers at Symantec, ESET, Stairwell, and RedCanary among others who've contributed samples, time, and expertise.
